Story highlights

The planet is the most Earth-like yet found in the habitable zone of a star like ours

It's about 60% larger than our own planet and "almost certainly has an atmosphere"

(CNN) — NASA said Thursday that its Kepler spacecraft has spotted "Earth's bigger, older cousin": the first nearly Earth-size planet to be found in the habitable zone of a star similar to our own.

Though NASA can't say for sure whether the planet is rocky like ours or has water and air, it's the closest

Space news

- Dynamic programming language
 - Code is accumulated by dynamic loading
 - e.g. eval, mashups

- Dynamic programming language
 - Code is accumulated by dynamic loading
 - e.g. eval, mashups
- JavaScript has no security awareness
 - No namespace or encapsulation management
 - Global scope for variables/ functions
 - All scripts have the same authority

- Dynamic programming language
 - Code is accumulated by dynamic loading
 - e.g. eval, mashups
- JavaScript has no security awareness
 - No namespace or encapsulation management
 - Global scope for variables/ functions
 - All scripts have the same authority

Problems

- 1 Side effects may cause unexpected behavior
- 2 Program understanding and maintenance is difficult
- 3 Libraries may get access to sensitive data
- 4 User code may be prone to injection attacks

Key challenges of present research

- All-or-nothing choice when including code
- Isolation guarantees noninterference
- Some scripts must have access the application state or are allowed to change it

Goals

- 1 Manage untrusted JavaScript Code
- 2 Control the use of data by included scripts
- 3 Reason about effects of included scripts

Shortcomings

- Static verifiers are imprecise because of JavaScript's dynamic features or need to restrict JavaScript's dynamic features
 - Interpreter modifications guarantee full observability but need to be implemented in all existing engines
-
- Implemented as a library in JavaScript
 - Library can easily be included in existing projects
 - All aspects are accessible through an API
 - No source code transformation or change in the JavaScript run-time system is required

JSConTest

Access Permission Contracts for Scripting Languages

- Investigate effects of unfamiliar function
- Type and effect contracts with run-time checking
- Summarizes observed access traces to a concise description
- Effect contracts specifying allowed access paths

Type and effect contracts

```
/*c (obj, obj) -> any with [x.b,y.a] */
function f(x, y) {
  y.a = 1;
  y.b = 2; X violation
}
```

- Implemented by an offline code transformation
 - Partial interposition (dynamic code, *eval*, **with**, ...)
 - Tied to a particular version of JavaScript
 - Transformation hard to maintain
- Special contract syntax
 - Requires a special JavaScript parser
- Efficiency issues
 - Naive representation of access paths
 - Wastes memory and impedes scalability

JSConTest2

Efficient Access Analysis Using JavaScript Proxies

Redesign and reimplement of JSConTest based on JavaScript proxies

Advantages

- Full interposition for the full language
 - Including dynamically loaded code and eval
- Safe for future language extensions
 - No transformation to maintain
- Runs faster in less memory
 - Efficient representation of access paths
 - Incremental path matching
- Maintenance is simplified
 - No custom syntax for contracts

Contracts on Objects

```
var obj = APC.permit('(a.?+b*)', {a:{b:5},b:{b:11}});
a = obj.a; // APC.permit('?', {b:5});
a.b = 3;
```

- APC encapsulates JSConTest2
- *permit* wraps an object with a permission. Arguments:
 - 1 Permission encoded in a string
 - 2 Object that is protected by the permission
- Contract specifies permitted access paths
 - Last property is readable/ writeable
 - Prefix is read-only
 - Not addressed properties are neither readable nor writeable
 - Read-only paths possible (@ denotes a non-existing property)

Contract: $\mathcal{C}$

Path: $\mathcal{P}$

- Implementation based on the JavaScript Proxy API
- Shortcomings of previous, translation-based implementation avoided
- Full interposition of contracted objects
 - Proxy intercepts all operations
 - Proxy-handler contains a contract and a path set
 - Forwards the operation or signals a violation
- Returned object contains the remaining contract (*Membrane*)
- Access contracts are regular expressions on literals
 - Each literal defines a property access
 - The language defines a set of permitted access paths

TreatJS

Higher-Order Contracts for JavaScript

- Language embedded contract system for JavaScript
- Enforced by run-time monitoring
- Specifies the interface of a software component
- Pre- and postconditions
- Standard abstractions for higher-order-contracts (base, function, and dependent contracts) [Findler,Felleisen'02]
- Systematic blame calculation
- Side-effect free contract execution
- Contract constructors generalize dependent contracts

Base Contract [Findler,Felleisen'02]

- *Base Contracts* are built from predicates
- Specified by a plain JavaScript function

```
function isNumber (arg) {  
  return (typeof arg) === 'number';  
};  
var _Number_ = Contract.Base(isNumber);  
  
assert(1, _Number_); ✓  
assert('a', _Number_); ✗ blame the subject
```

- Subject v gets blamed for *Base Contract* $\mathcal{B}$ iff:
 $\mathcal{B}(v) \neq \text{true}$

Function Contract [Findler,Felleisen'02]

```
//  $\text{Number} \times \text{Number} \rightarrow \text{Number}$   
function plus (x, y) {  
  return (x + y);  
}
```

Function Contract [Findler,Felleisen'02]

```
//  $Number \times Number \rightarrow Number$   
function plus (x, y) {  
  return (x + y);  
}
```

```
var plus = assert(plus, Contract.Function([_Number_,  
  _Number_], _Number_));
```

Function Contract [Findler,Felleisen'02]

```
// Number × Number → Number  
function plus (x, y) {  
  return (x + y);  
}
```

plus('a', 'a'); **✗** *blame the context*

- Context gets blamed for $C \rightarrow C'$ iff:
Argument x gets *blamed* for C (as subject)

Function Contract [Findler,Felleisen'02]

```
// Number × Number → Number
function plusBroken (x, y) {
  return (x>0 && y>0) ? (x + y) : 'Error';
}
```

plusBroken(0, 1); **✗** *blame the subject*

- Subject f gets blamed for $C \rightarrow C'$ iff:
 $\neg (\text{Context gets } \textit{blamed } C) \wedge (f(x) \text{ gets } \textit{blamed } C')$

New!

Overloaded Operator

- Function *plus* works for strings, too
- Requires to model overloading and multiple inheritances

```
// Number × Number → Number
```

```
function plus (x, y) {  
  return (x + y);  
}
```

```
plus('a', 'a'); ✗ blame the context
```

- No support for arbitrary combination of contracts
- Racket supports `and/c` and `or/c`
- Attempt to extend conjunction and disjunction to higher-order contracts

- and/c tests any contract
- no value fulfills Number and String at the same time

```
(and/c (Number × Number → Number) (String × String → String))  
function plus (x, y) {  
  return (x + y);  
}
```

plus('a', 'a'); ✗ *blame the context*

- or/c checks first-order parts and fails unless exactly one (range) contract remains
- Work for disjoint base contracts
- No combination of higher-order contracts
- No support for arbitrary combinations of contracts

$(\text{or/c } (\text{Number} \times \text{Number} \rightarrow \text{Number}) (\text{String} \times \text{String} \rightarrow \text{String}))$

```
function plus (x, y) {  
  return (x + y);  
}
```

plus('a', 'a'); ✓

- Support for arbitrary combination of contracts
 - Combination of base and function contracts
 - Combination of function contracts with a different arity
- Intersection and union contracts
- Boolean combination of contracts

```
// ( $\text{Number} \times \text{Number} \rightarrow \text{Number}$ )  $\cap$  ( $\text{String} \times \text{String} \rightarrow \text{String}$ )  
function plus (x, y) {  
  return (x + y);  
}
```

Intersection Contract

```
// (Number × Number → Number) ∩ (String × String → String)
function plus (x, y) {
  return (x + y);
}
```

```
var plus = assert(plus, Contract.Intersection(
  Contract.Function([_Number_, _Number_], _Number_)
  Contract.Function([_String_, _String_], _String_));
```

Intersection Contract

```
// (Number × Number → Number) ∩ (String × String → String)  
function plus (x, y) {  
  return (x + y);  
}
```

plus(true, true); ✗ *blame the context*

- Context gets blamed for $\mathcal{C} \cap \mathcal{C}'$ iff:
(Context gets *blamed* for $\mathcal{C}$) $\wedge$ (Context gets *blamed* for $\mathcal{C}'$)

Intersection Contract

```
// (Number × Number → Number) ∩ (String × String → String)  
function plusBroken (x, y) {  
  return (x>0 && y>0) ? (x + y) : 'Error';  
}
```

plusBroken(0, 1); *✗ blame the subject*

- Subject f gets *blamed* for $\mathcal{C} \cap \mathcal{C}'$ iff:
(f gets *blamed* for $\mathcal{C}$) $\vee$ (f gets *blamed* for $\mathcal{C}'$)

- A failing contract must not signal a violation immediately
- Violation depends on combinations of failures in different sub-contracts

```
// (Number → Number) ∩ (String → String)
```

```
function addOne (x) {  
  return (x + 1);  
}
```

```
addOne('a');
```

- A failing contract must not signal a violation immediately
- Violation depends on combinations of failures in different sub-contracts

```
// (Number → Number) ∩ (String → String)
```

```
function addOne (x) {  
  return (x + 1);  
}
```

```
addOne('a');
```

- A failing contract must not signal a violation immediately
- Violation depends on combinations of failures in different sub-contracts

```
// (Number → Number) ∩ (String → String)
```

```
function addOne (x) {  
  return (x + 1);  
}
```

```
addOne('a'); ✓
```

- Contract assertion must connect each contract with the enclosing operations
- *Callback* implements a constraint and links each contracts to its next enclosing operation
- Reports a record containing two fields, *context* and *subject*
- Fields range over $\mathbb{B}_4 = \{\perp, f, t, \top\}$ [Belnap'1977]

Non-Interference

- No syntactic restrictions on predicates
- Problem: Contract may interfere with program execution
- Solution: Predicate evaluation takes place in a sandbox

```
function isNumber (arg) {  
  type = (typeof arg);  
  return type === 'number';  
};
```

```
var _Number_ = Contract.Base(isNumber);
```

Non-Interference

- No syntactic restrictions on predicates
- Problem: Contract may interfere with program execution
- Solution: Predicate evaluation takes place in a sandbox

```
function isNumber (arg) {  
  type = (typeof arg); ✗ access forbidden  
  return type === 'number';  
};
```

```
var _Number_ = Contract.Base(isNumber);
```

```
assert(1, _Number_);
```

- All contracts guarantee noninterference
- Read-only access is safe

```
var _Array_ = Contract.Base(function (arg) {  
  return (arg instanceof Array); ✗ access forbidden  
});
```

- All contracts guarantee noninterference
- Read-only access is safe

```
var _Array_ = Contract.Base(function (arg) {  
    return (arg instanceof OutsideArray); ✓  
});
```

```
var _Array_ = Contract.With({ OutsideArray:Array}, _Array_);
```

- Building block for dependent, parameterized, abstract, and recursive contracts
- Constructor gets evaluated in a sandbox, like a predicate
- Returns a contract
- No further sandboxing for predicates

```
var __Type__ = Contract.Constructor(function (type) {  
  return Contract.Base(function (arg) {  
    return (typeof arg) === type;  
  });  
});
```

```
var _Number_ = __Type__('number');
```

TreatJS-Sandbox

Transaction-based Sandboxing of JavaScript

- Language-embedded sandbox for full JavaScript
- Inspired by JSConTest2 and Revocable References
- Adapts SpiderMonkey's compartment concept to run code in isolation to the application state
- Provides features known from transaction processing in database systems and transactional memory

- A reference is the right to access an object
- Requires to control property read and property write

Sandbox Encapsulation

- 1 Place a write protection on objects
- 2 Remove external bindings of functions

Identity Preserving Membrane

- Function decompilation uses the **Function.prototype.toString** method to return a string that contains the source code of that function
- Applying *eval* to the string creates a fresh variant
- A **with** statement places a proxy in top of the scope chain
- The *hasOwnProperty* trap always returns true

JavaScript Scope Chain

```
var x = 1;
```

```
function f (y){
```

```
  function g () {  
    var z = 1;  
    return x+y+z;  
  }
```

```
}
```

Sandbox Scope Chain

```
var x = 1;
```

```
with(sbxglobal){
```

```
  function g () {  
    var z = 1;  
    return x+y+z;  
  }
```

```
}
```

- JSConTest/ JSConTest2: Effect monitoring for JavaScript
- Enables to specify effects using access permission contracts
- TreatJS: Language embedded, dynamic, higher-order contract system for full JavaScript
- Support for intersection and union contracts
- Contract constructors with local scope
- Sandbox: Language embedded sandbox for full JavaScript
- Runs code in a configurable degree of isolation
- Provides a transactional scope

- Temporal/ Computation Contracts
- Lemma Contracts
- Invariants
- Different blaming semantics (Lax, Picky, Indy)

Limitations

- Dynamic contract checking impacts the execution time
- Arbitrary combinations of contracts lead to unprecise error messages

- 1 Hybrid contract checking
- 2 Static pre-checking of contracts
- 3 Optimization, contract rewriting

Appendix

JSConTest

Access Permission Contracts for Scripting Languages

JSConTest2

Efficient Access Analysis Using JavaScript Proxies

Redesign and reimplementaion of JSConTest based on JavaScript proxies

Redesign and reimplement of JSConTest based on JavaScript proxies

Advantages

- Full interposition for the full language
 - Including dynamically loaded code and eval
- Safe for future language extensions
 - No transformation to maintain
- Runs faster in less memory
 - Efficient representation of access paths
 - Incremental path matching
- Maintenance is simplified
 - No custom syntax for contracts

Contracts on Functions

```
var func = APC.permitArgs('arguments.0.(a.?+b*)',  
function(arg0) {  
    // do something  
});
```

- *permitArg* wraps a function with permissions
 - 1 contract applied to function arguments
 - 2 function
- Arguments accessed by position *arguments.0*
 - No reliable way to access parameter names
 - Function may use unlisted parameters
 - Parameter names may not be unique

Interaction of Contracts

```
var obj = APC.permit('((a+a.b)+b.b.@)', {a:{b:3}, b:{b:5}});  
obj.a = obj.b; // APC.permit('b.@', {b:5});  
y = obj.a; // APC.permit('b & b.@', {b:5});  
y.b = 7; ✗ violation
```

- Line 2 reads *obj.b* and writes *obj.a*
- Afterwards, *obj.b* and *obj.a* are aliases
- JSConTest2 enforces *both* contracts reaching *obj.b* and *obj.a*
- *obj.a* carries contract $!(\epsilon + b) \& b.@ = !b.@$
- Thus, writing to *obj.a.b* is not permitted

- 1 Cannot directly protect DOM objects because of the browser's sandbox
- 2 Proxies are not transparent with respect to equality, i.e. for distinct proxies `==` and `===` returns false, even if the target object is the same

TreatJS

Higher-Order Contracts for JavaScript

- Defined by a mapping from property names to contracts
- Represented as a pair of a *getter* and a *setter* function
- *Getter* and *Setter* apply the property's contract

```
var arraySpec = Contract.AObject({length:_Number_});
```

- Defined by a mapping from property names to contracts
- Represented as a pair of a *getter* and a *setter* function
- *Getter* and *Setter* apply the property's contract

```
var arraySpec = Contract.AObject({length:_Number_});
```

```
var faultyObj = assert({length:'1'}, arraySpec);
```

- Defined by a mapping from property names to contracts
- Represented as a pair of a *getter* and a *setter* function
- *Getter* and *Setter* apply the property's contract

```
var arraySpec = Contract.AObject({length: _Number_});
```

```
var faultyObj = assert({length: '1'}, arraySpec);
```

```
var faultyObj.length; X blame the subject
```

- Defined by a mapping from property names to contracts
- Represented as a pair of a *getter* and a *setter* function
- *Getter* and *Setter* apply the property's contract

```
var arraySpec = Contract.AObject({length:_Number_});
```

```
var faultyObj = assert({length:'1'}, arraySpec);
```

```
var faultyObj.length = '2'; ✗ blame the context
```

- *Function Contract* is build from one contract for the domain and one contract for the range of a function
- An *Object Contract* serves as the domain portion of a *Function Contract* with zero or more arguments
- **AFunction** defines an *Object Contract* from the array

Contract.AFunction([_Number_, _Number_], _Number_);

- *Function Contract* is build from one contract for the domain and one contract for the range of a function
- An *Object Contract* serves as the domain portion of a *Function Contract* with zero or more arguments
- **AFunction** defines an *Object Contract* from the array

```
Contract.AFunction([_Number_, _Number_], _Number_));
```

```
Contract.Function(  
  Contract.AObject([_Number_, _Number_]), _Number_));
```

Recursive Contract

- Similar to *Constructors*
- Unrolls the constructor when asserted
- Contract is given as argument to the constructor

```
var __LinkedList__ = Contract.Recursive(  
  Contract.Constructor(function(__LinkedList__) {  
    return Contract.AObject({  
      value:__Number_,  
      next:__LinkedList__});  
  }));
```

```
// (Number  $\times$  Number  $\rightarrow$  Number)  $\cup$  (Number  $\times$  Number  $\rightarrow$  String)
function plusBroken (x, y) {
  return (x>0 && y>0) ? (x + y) : 'Error';
}
```

```
// (Number × Number → Number) ∪ (Number × Number → String)
function plusBroken (x, y) {
  return (x>0 && y>0) ? (x + y) : 'Error';
}
```

```
var plusBroken = assert(plusBroken, Contract.Union(
  Contract.Function([_Number_, _Number_], _Number_)
  Contract.Function([_Number_, _Number_], _String_));
```

```
// (Number × Number → Number) ∪ (Number × Number → String)

Story highlights

The planet is the most Earth-like yet found in the habitable zone of a star like ours

It's about 60% larger than our own planet and "almost certainly has an atmosphere"

Though NASA can't say for sure whether the planet is rocky like ours or has water and air, it's the closest

(CNN) — NASA said Thursday that its Kepler spacecraft has spotted "Earth's bigger, older cousin": the first nearly Earth-size planet to be found in the habitable zone of a star similar to our own.

Non-interfering Contract Execution

```
var _Number_ = Contract.Base(function (arg) {  
  type = (typeof arg);  
  return type === 'number';  
});
```

Non-interfering Contract Execution

```
var _Number_ = Contract.Base(function (arg) {  
  type = (typeof arg);  
  return type === 'number';  
});
```

Read-only access

```
var _Array_ = Contract.Base(function (arg) {  
  return (arg instanceof OutsideArray);  
});  
var _Array_ = Contract.With({OutsideArray:Array}, _Array_);
```

Application Scenarios

TreatJS Online

TreatJS: Higher-Order Contracts for JavaScript

Online Version

[TreatJS Home](#) [Documentation](#) [TreatJS Sample Applications](#) [Download TreatJS](#)

Write your JavaScript program:

```
function f ( x, y ) {  
  return (x+y);  
}  
  
var g = Contract.eset({ f,  
  Contract.AFunction([typeofNumber, typeofNumber], typeofNumber) });  
  
return g ( 3, "5" );
```

[Run Code](#) [Make Log](#) [Manual](#) [Predefined Contracts](#) [Clean](#)

Output:

```
Contract Violation: ([ [ 5:[typeofNumber] ],[typeofNumber] ]->[typeofNumber])  
Name is not called  
Caller: <Failure>  
Callee: <Unknown>  
Reconnect: <Failure>
```

TreatJS: Higher-Order Contracts for JavaScript, Version 1.2.10

Copyright © 2014, Prof. Dr. Peter Thiemann, University of Freiburg
by Matthias Keil and Peter Thiemann

Running Example

```
function Node (value, left, right) {  
  this.value = value;  
  this.left = left;  
  this.right = right;  
}  
  
function heightOf (node) {  
  return node ? Math.max(heightOf(node.left)+1, heightOf(  
    node.right)+1) : -1;  
}  
  
function setValue (node) {  
  node.value=heightOf(node);  
  if(node.left) setValue(node.left);  
  if(node.right) setValue(node.right);  
}
```

```
var root = new Node(0, new Node(0), new Node(0));
```

```
var root = new Node(0, new Node(0), new Node(0));
```

```
var sbx = new Sandbox(this, { /* some parameters */ });
```

```
var root = new Node(0, new Node(0), new Node(0));
```

```
var sbx = new Sandbox(this, { /* some parameters */ });
```

```
sbx.call(heightOf, this, root);
```

Cross-Sandbox Access

Read Access

```
function heightOf (node) {  
  return node ? Math.max(heightOf(node.left)+1, heightOf(  
    node.right)+1) : -1;  
}
```

Cross-Sandbox Access

Read Access

```
function heightOf (node) {  
  return node ? Math.max(heightOf(node.left)+1, heightOf(  
    node.right)+1) : -1;  
}
```

Cross-Sandbox Access

Read Access

```
function heightOf (node) {  
  return node ? Math.max(heightOf(node.left)+1, heightOf(  
    node.right)+1) : -1;  
}
```

Cross-Sandbox Access

Write Access

```
function setValue (node) {  
  node.value=heightOf(node);  
  if(node.left) setValue(node.left);  
  if(node.right) setValue(node.right);  
}
```

Cross-Sandbox Access

Write Access

```
function setValue (node) {  
  node.value=heightOf(node);  
  if(node.left) setValue(node.left);  
  if(node.right) setValue(node.right);  
}
```

Cross-Sandbox Access

Write Access (cont'd)

```
var sbx2 = new Sandbox(this, { /* some parameters */ });  
function appendRight (node) {  
    node.right = Node('a', Node('b'), Node('c'));  
}  
sbx2.call(appendRight, this, root);
```

Effect Monitoring

Read Effects

```
sbx.effectsOf(this).foreach(function(i, e) {print(e)});
```

;;; Effects of this

(1425301383541) has [name=heightOf]

(1425301383541) get [name=heightOf]

(1425301383543) has [name=Math]

(1425301383543) get [name=Math]

Effect Monitoring

Write Effects

```
sbx.writeeffectsOf(root).foreach(function(i, e) {print(e)});
```

```
;;; Write Effects of root  
(1425301634992) set [name=value]
```

Inspecting a Sandbox

Changes

```
sbx.hasChanges; // returns true
sbx.changes.foreach(function(i, e) {print(e)});
```

;;; All Changes

Change: (1425300876577) set [name=value]@SBX001

Inspecting a Sandbox

Differences

```
sbx.hasDifferences; // returns true
sbx.differences.foreach(function(i, e) {print(e)});
```

```
;;; Differences of root
```

```
Difference: (1425300932388) set [name=value]@SBX001
```

Inspecting a Sandbox

Differences

```
sbx.hasDifferences; // returns true  
sbx.differences.foreach(function(i, e) {print(e)});
```

```
;;; Differences of root
```

```
Difference: (1425300932388) set [name=value]@SBX001
```

Inspecting a Sandbox

Conflicts

```
sbx.inConflictWith(sbx2); // returns true
sbx.conflictsWith(sbx2).foreach(function(i, e) {print(e)});
```

Conflict: (1425303937853) get [name=right]@SBX001 –
(1425303937855) set [name=right]@SBX002

Transaction Processing

Commit

```
sbx.commit();
```

Transaction Processing

Rollback

```
sbx.rollback();
```

Transaction Processing

Revert

```
sbx.revert();
```

- Fine-grained handling of commit, rollback and revert
- Transparent sandboxing
- Snapshot Mode
- Wrapping of values

Sandbox Scope Chain

```
var node = new Node(/*some sub-nodes */);  
var sbx = new Sandbox(this, /*some parameters */);
```

```
with(sbxglobal){
```

```
function setValue (node) {  
  node.value=heightOf(node);  
  setValue(node.left);  
  setValue(node.right);  
}
```

```
}
```

- A new sandbox starts with a blank environment
- Read access by binding values when instantiating a new sandbox
- Fine-grained write access by committing effects
- Combination with *Access Permission Contracts* and *Revocable References* possible

- Enables scripts to run in a configurable degree of isolation
- Enables fine-grained access control
- Provides a transactional scope that performs effect logging
- Effects can be committed to the application state or rolled back

- Function recompilation needs a string that contains the source code of that function
- **Function**.*prototype.toString* did not work for all functions
 - A native function did not have a string representation
 - The **Function**.*prototype.bind* method creates a new bound function without a string representation
